Abstract: According to statistics from the World Health Organisation (WHO), 2.3 million women worldwide were diagnosed with breast cancer in 2020; 685,000 of these cases ended in death. In the continuous fight against breast cancer, it is critical to investigate innovative approaches as the disease's incidence numbers continue to grow. As a result, ethyl 3-formyl-1H-indole-2-carboxylate 1 was reacted with thiosemicarbazide and semicarbazide to create a variety of novel indolyl-hydrazones. The new hit compounds were obtained by combining HCl, 4-nitrophenylhydrazine, 2-dinitrophenylhydrazine, and 4-amino-5-(1H-indol-2-yl)-1,2,4-triazole-3-thione. By using NMR, elemental analysis, and X-ray single-crystal analysis, these compounds were given chemical structures. The compounds' cytotoxicity against breast cancer cells (MCF-7) was examined using the MTT test. In contrast to staurosporine (IC₅₀ = 8.32±0.43 μM), cytotoxicity data showed strong IC₅₀ values against MCF-7, particularly compounds 5, 8, and 12, with IC₅₀ values of 2.73±0.14, 4.38±0.23, and 7.03±0.37 μM, respectively. Thus, the wound-healing test was used to examine the activities of compounds 5, 8, and 12 in connection to cell migration. With corresponding percentages of wound closure recorded at 48.8%, 60.7%, and 51.8%, the results demonstrated noteworthy wound-healing effectiveness. By looking at the compounds' ability to induce apoptosis, the effect of the hit compounds on proliferation was evaluated. Remarkably, compound 5 significantly increased cell death in MCF-7 cells, showing a noteworthy 39.26% increase compared to the untreated control group, which showed just 1.27% cell death. Additionally, compound 5's mode of action was examined by testing it against kinase receptors. When compared to conventional medications that target these receptors, the findings showed promising efficacy and considerable kinase inhibition, especially against PI3K-α, PI3K-β, PI3K-δ, CDK2, AKT-1, and EGFR. Using an in vivo experiment, compound 5 showed a significant decrease in tumour volume in the concluding phase, going from 106 mm³ in the untreated control to 56.4 mm³. Additionally, it greatly reduced tumour growth by 46.9%. Because they successfully prevent both cell migration and proliferation, the found leads show promise for possible development into future drugs for the treatment of breast cancer in light of these results.

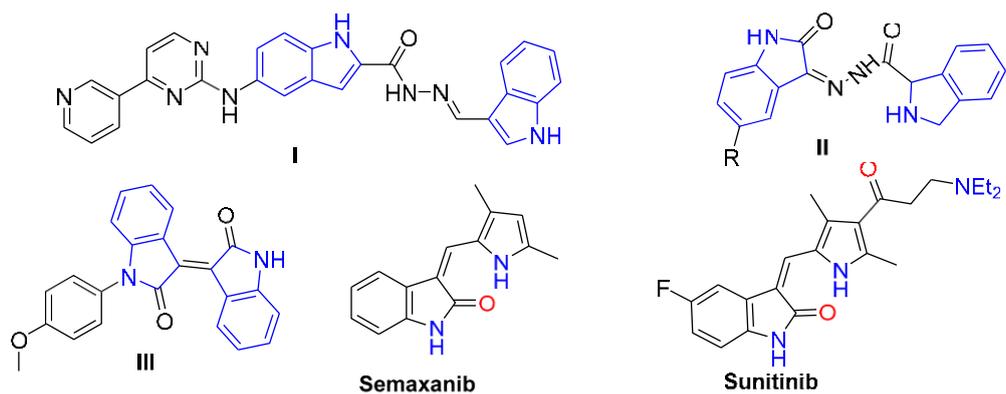

Keywords: indole; hydrazone; MCF7; anticancer; apoptosis; kinase inhibition

1. Introduction

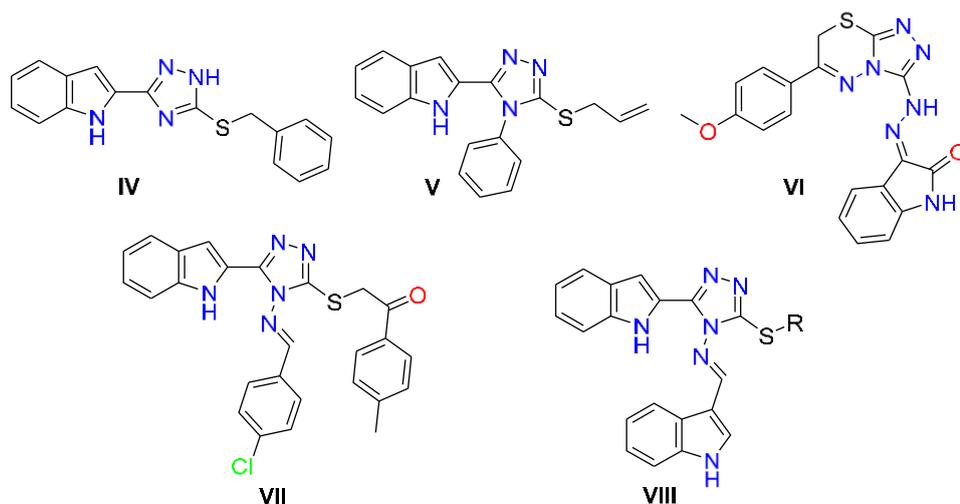

Cancer is the biggest cause of death worldwide, and breast cancer is one of the top causes of death for women. The intricacy of this condition is a major obstacle to medical treatment. Conventional anticancer therapies have the potential to eradicate cancer cells, but they often cause a host of negative side effects that harm healthy organs. Conventional antitumor medications, which block certain chemicals that promote tumour development, often have adverse effects. As a result, researchers are working hard to develop new anticancer medications and create molecules that are specifically suited to treating different kinds of cancer. The goal of this endeavour is to find tailored medicines that may provide less hazardous and more effective therapeutic alternatives [1,2]. Kinases are essential for cellular activity and make up the sixth biggest family of proteins in the human body [3–5]. Because they regulate kinase dysregulation linked to a number of illnesses and disorders, such as cancer, inflammatory conditions, and reactions to external stimuli, kinase inhibitors are essential for preserving appropriate cellular functions. These inhibitors successfully prevent their substrates' development by controlling protein kinases, which allows them to regulate the survival and proliferation of cells [6–9]. Kinase inhibitors may target a wide range of particular targets, including EGFR, CDK, AKT, PI3K, and others [10–12]. Researchers have been interested in indole-containing chemicals for a long time, and the area has developed into a lively one. The creation of novel bioactive drugs is made possible by the indole moiety's high affinity for binding to a variety of receptors. Its extensive use in target-based discovery and anticancer drug design is well-established [13–18]. (4-(pyridin-3-yl)pyrimidin-2-yl)amino-1H-indole-2-carbohydrazide N'-Methylene-5- (Hu et al. [19] reported that the moiety exhibited CDK9 inhibitory action for cancer therapeutic treatment. Compound I, one of the illustrative possibilities presented, was evaluated and shown to have promise against CDK9 inhibition. According to Al-Warhi et al., oxindole II exhibited anti-tumor action by targeting the CDK4 inhibitor [20]. Zhao et al. developed, synthesised, and physiologically evaluated N-substituted iso-indigo compounds as cyclin-dependent kinase 2 (CDK2) inhibitors. It was discovered that iso-indigo compound III halted the cell cycle's S-phase [21]. (Fig. 1).

Advanced renal cell carcinoma (RCC) and gastrointestinal stromal tumours (GIST) are treated with sunitinib [22–25]. Tyrosine kinase inhibitors like semaxanib are utilised in cancer treatments [26]. The indole-triazolealkylated system (Figure 1) demonstrated notable anti-cancer properties. For instance, 3-(allylsulfanyl)-4-phenyl-5-(1H-indol-2-yl) and 3-benzylsulfanyl-5-(1H-indol-2-yl)-2H-1,2,4-triazole IV shown encouraging antiproliferative efficacy against HEPG-2 and MCF-7 cancer cell lines [27]. The anti-proliferative efficacy of 1,2,4-triazole V and its analogues against breast cancer was intriguing [28]; it replaced 3-(triazolo-thiadiazin-3-yl)-indolin-2-one compounds. Indole-triazole hybrid VII and its analogues demonstrated a strong inhibition against vascular endothelial growth factor receptor-2 (VEGFR-2), with possible anti-renal cancer activity [30]. VI also demonstrated dual inhibition activity for c-Met (a receptor tyrosine kinase) and VEGFR2 enzymes, with an effective anti-proliferative potential against different subpanels of the most NCI58 tumour cell lines [29]. By inhibiting VEGFR2 tyrosine kinase, alkylated indolyl-triazole Schiff bases VIII targeted breast cancer [31].

The idea of creating new compounds that combine esters and azomethine groups with an indole scaffold in one molecule is anticipated to provide powerful anticancer medications, building on the results of the previously described investigations. This expectation is based on the chemicals' ability to interact with receptors as both donors and/or acceptors of hydrogen bonds.

Selected FDA approved indole containing drugs and kinase inhibitors

Indole-triazole hybrids disclosed anticancer activity

2. Results and Discussion

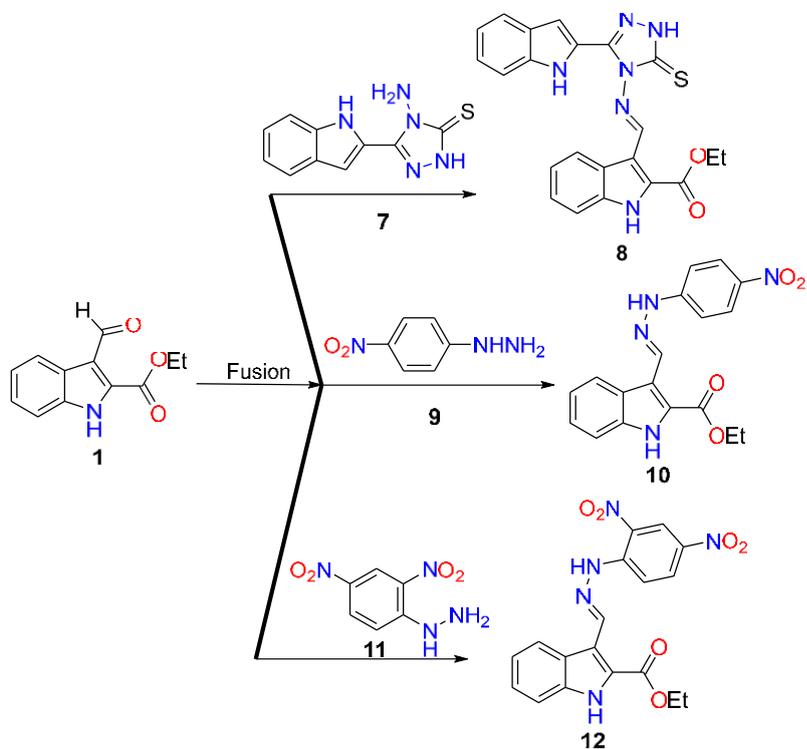

Synthesis

Condensation of thiosemicarbazide **2** with ethyl 3-formyl-1H-indole-2-carboxylate **1** by fusion for 5 min led to the formation of the thiosemicarbazone derivative **3**. Under the same fusion condition, the condensation of **1** with semicarbazide.HCl **4** interestingly afforded bis-ester derivative **5**. Through the reaction of **1** with semicarbazide.HCl **4** under reflux in AcOH/MeOH, semicarbazone derivative **6** was obtained (Scheme 1).

Scheme 1. Reaction of thiosemicarbazide 2 and semicarbazide.HCl 4 with ethyl 3-formyl-1H-indole-2-carboxylate 1.

Under fusion conditions, the reaction between ethyl 3-formyl-1H-indole-2-carboxylate 1 with amine functionality derivatives, such as 4-amino-5-(1H-indol-2-yl)-1,2,4-triazole-3-thione 7, 4-nitrophenyl hydrazine 9, and 2,4-dinitrophenyl hydrazine 11, resulted in the formation of condensed hydrazones 8, 10, and 12, respectively (Scheme 2). The structural assignment for the newly synthesized hydrazones was established through a comprehensive set of spectroscopic tools (see Section 3), which included nuclear magnetic resonance (NMR), mass spectrometry (MS), CHN analysis, and single-crystal X-ray diffraction analysis.

Scheme 2. Synthesis of hydrazones 8, 10, and 12.

X-ray Single-Crystal Analysis for Compounds 3 and 5

Using single-crystal X-ray analysis, structures of compounds 3 and 5 were conclusively confirmed. The unit cell parameters of compound 3 ($a = 9.23490(10) \text{ \AA}$, $b = 19.4168(2) \text{ \AA}$, $c = 7.89280(10) \text{ \AA}$, and $V = 1374.36(3) \text{ \AA}^3$) that crystallized in monoclinic space group $P2_1/c$ and compound 5 ($a = 5.4774(3) \text{ \AA}$, $b = 9.2031(5) \text{ \AA}$, $c = 10.6234(8) \text{ \AA}$, and $V = 531.26(6) \text{ \AA}^3$) that crystallized in the triclinic space group $P\bar{1}$ (Table 1). The crystal structure (Figure 2) revealed that compound 3 was a thiosemicarbazone structure, while compound 5 was a bis-hydrazino derivative.

Biology

MTT Assay for the Synthesized Compounds

The produced compounds were examined for their cytotoxicity against MCF-7 breast cancer cells using the MTT assay. As summarized in Table 2, they demonstrated potent IC_{50} values against MCF-7, especially compounds 5, 8, and 12, with IC_{50} values of 2.73 ± 0.14 , 4.38 ± 0.23 , and $7.03 \pm 0.37 \mu M$, compared to staurosporine, with an IC_{50} value of $8.32 \pm 0.43 \mu M$, while compounds 1, 3, and 6 exhibited promising cytotoxicity, with IC_{50} values of 19.7 ± 2.31 , 10.2 ± 0.53 , and $9.42 \pm 0.57 \mu M$, respectively. Compound 10 exhibited moderate cytotoxicity, with a high concentration of IC_{50} ($25.4 \pm 1.54 \mu M$).

Table 2. Cytotoxicities of the investigated compounds against MCF-7 cells using the MTT assay.

Compounds	$IC_{50} \pm SD [\mu M]$
1	19.7 ± 2.31
3	10.2 ± 0.53
5	2.73 ± 0.14
6	9.42 ± 0.57
8	4.38 ± 0.23
10	25.4 ± 1.54
12	7.03 ± 0.37
Staurosporine	8.32 ± 0.43

IC_{50} values were calculated using "Mean \pm SD" of three independent values.

Wound-Healing Activity

As shown in Table 3 and Figure 3, the wounded area between cell layers following a scratch was partially filled by migrating MCF-7 control cells (94.07% wound closure), while treatments of compounds 5, 8, and 12 significantly inhibited wound-healing activity, with percentages of wound closure of 48.88, 60.74, and 51.85%, respectively, compared to control.

Table 3. The percentage of wound healing (% closure) for untreated and 5-treated MCF-7 cells.

Compound	% Closure*, MCF-7
5	$48.88^{\#} \pm 2.7$
8	$60.74^{\#} \pm 3.43$
12	$51.85^{\#} \pm 2.92$
Untreated control	94.07 ± 5.5

* Values are expressed as "Mean \pm SD". # Significance level ($p < 0.05$) indicates a significant difference (unpaired Student's *t*-test) from the untreated control group. Data for length of migration (mm) and area are supported in the Supplementary Materials.

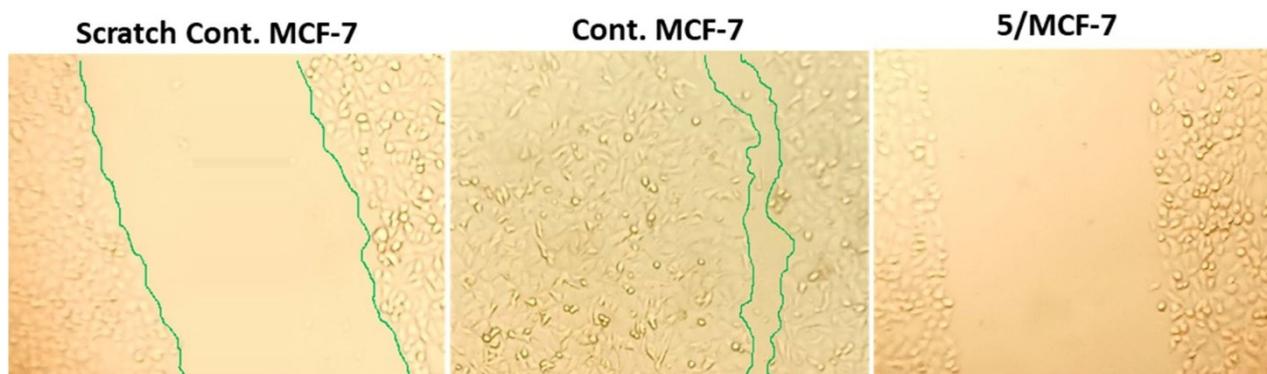

Figure 3. Migration of MCF-7 cells treated with compound 5 for 72 h observed under a light microscope as detected by the wound-healing assay.

Apoptotic Induction Activity

To investigate the apoptotic activity of compounds 5, 8, and 12, flow cytometric evaluation of Annexin V/PI staining was utilized to examine apoptotic cell death in untreated and treated MCF-7 cells. Table 4 shows that compound 5 dramatically increased cell death in MCF-7 cells by 39.26% (29.35% for apoptosis and 9.91% for necrosis), compared to the untreated control group, which increased it by 1.27% (0.4% for apoptosis and 0.87% for necrosis). Additionally, compounds 8 and 12 caused total cell death by 24.4% and 37%, with apoptosis ratios of 15.72% and 21.0%, respectively.

Table 4. Flow cytometry results of the three promising cytotoxic agents using Annexin V/PI and DNA-aided flow cytometry.

Compound	Annexin V/PI Staining				DNA Content			
	Total	Early	Late	Necrosis	%G0-G1	%S	%G2/M	%Pre-G1
Cont.MCF7	1.27	0.29	0.11	0.87	52.91	41.33	5.76	1.27
5	39.26	7.11	22.24	9.91	39.07	56.19	4.74	39.26
8	24.38	2.27	13.45	8.66	47.10	46.31	6.57	24.38
12	37.05	4.59	17.44	15.02	59.33	38.10	2.55	37.05

After being treated with a cytotoxic chemical, the cell population in each cell phase was then ascertained by DNA flow cytometry. Compound 5 increased the S-phase cell population by 56.2%, compared to control, which increased it by 41.33%, as Figure 4 illustrates, whereas cells in other phases decreased negligibly. Consequently, compound 5 stopped MCF-7 cells from proliferating at the S-phase by inducing apoptosis.

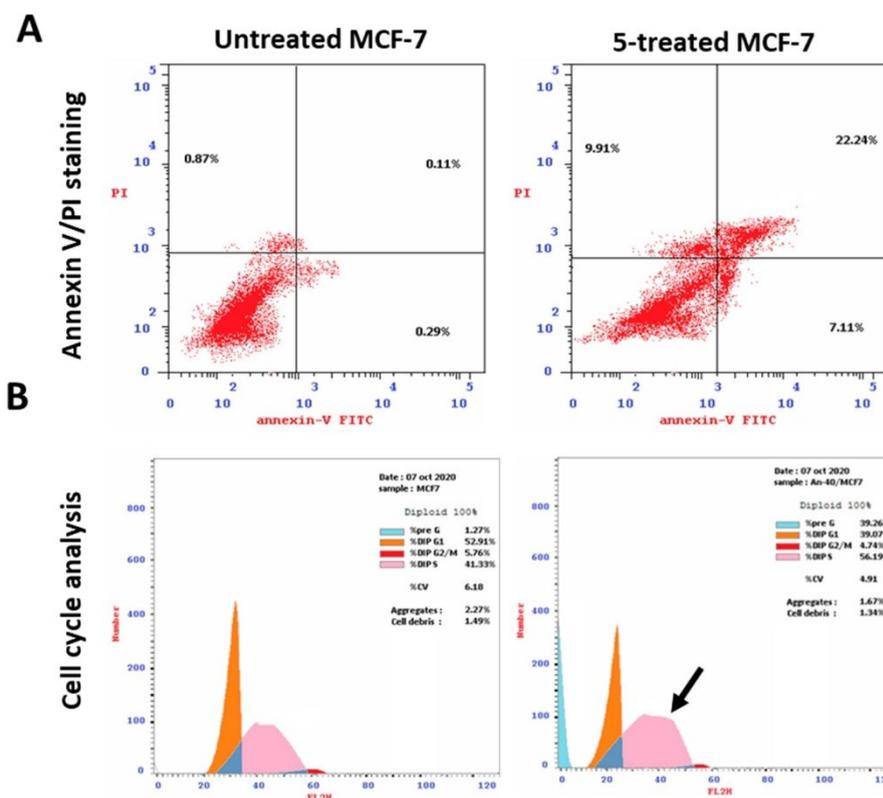

Figure 4. Analysis using flow cytometry. Upper panel (A): Annexin V/PI staining for evaluating necrosis and apoptosis, Q1; Early apoptosis is Q4, and late apoptosis is Q2. The DNA content histograms of untreated and 5-treated MCF-7 cells at each phase, "Pre-G, G1, G2/M, S" phases, with an IC₅₀ value of 2.73 μM, 48 h, are displayed in the lower panel (B).

Kinase-Inhibition Activity

To highlight their effective molecular target, the most cytotoxic and apoptotic compound 5 was screened for its activity towards a panel of kinase activities, including PI3K- α , PI3K- β , PI3K- δ , CDK2, AKT-1, and EGFR, compared to their standard drugs. It caused promising kinase inhibitory activities, as summarized in Table 5. Interestingly, compound 5 exhibited significant inhibitory potential against PI3K- α and showed selectivity, with a 4.92-fold higher potency than LY294002. However, in the cases of PI3K- β and PI3K- δ , compound 5 demonstrated lower activity compared to LY294002. Moreover, compound 5 ($IC_{50} = 0.156 \pm 0.01 \mu M$) showed a reactivity profile against CDK2 close to the standard drug erlotinib (IC_{50} of $0.173 \pm 0.01 \mu M$). On the other hand, compound 5 ($IC_{50} = 0.602 \pm 0.03 \mu M$) demonstrated lower reactivity towards AKT-1, compared to the standard drug A-674563 (IC_{50} of $0.26 \pm 0.01 \mu M$). Finally, compound 5 ($IC_{50} = 0.058 \pm 0.029 \mu M$) demonstrated lower reactivity against EGFR, compared to the standard drug erlotinib (IC_{50} of $0.038 \pm 0.019 \mu M$). Compound 5 was found to possess the potential for inhibiting multiple kinases.

Table 5. IC_{50} values of kinase activities of the tested compounds.

Compound	$IC_{50} [\mu M] \pm SD^*$					
	PI3K- α	PI3K- β	PI3K- δ	CDK2	AKT-1	EGFR
5	1.73 ± 0.1	2.27 ± 0.11	2.68 ± 0.15	0.156 ± 0.01	0.602 ± 0.03	0.058 ± 0.029
LY294002	8.52 ± 0.48	0.44 ± 0.02	0.85 ± 0.05	NT	NT	NT
erlotinib	NT	NT	NT	0.173 ± 0.01	NT	0.038 ± 0.019
A-674563	NT	NT	NT	NT	0.26 ± 0.01	NT

* "Values are expressed as an average of three independent replicates". IC_{50} values were calculated using a sigmoidal non-linear regression curve fit of percentage inhibition against five concentrations of each compound". NT = Not tested.

In Vivo (SEC-Bearing Mice)

A solid Ehrlich carcinoma cell was implanted, and 5 was injected intraperitoneally (IP) throughout the experiment to confirm its anticancer efficacy, as shown in Figure 5, which summarizes the main findings of the antitumor activity experiments. As a result, tumor proliferation revealed an increase in solid tumor mass of approximately 398.1 mg, which is related to tumor proliferation. Following treatment with 5, the solid tumor mass decreased to 126.5 mg, compared to 110 mg in the 5-FU treatment. As a result, treatments with 5 considerably reduced tumor volume from 10^6 mm^3 in the untreated control to 56.4 mm^3 and significantly decreased tumor proliferation by 46.9%, while 5-FU reduced tumor volume to 43.7 mm^3 and inhibited tumor development by 58.8%.

Molecular Docking

To illustrate the virtual mechanism of binding towards the EGFR, PI3K, and CDK2 binding sites, molecular docking research was carried out. As seen in Figure 6, compound 5 was properly docked inside the protein active sites of EGFR (A), PI3K (B), and CDK2 (C), with binding energies of -23.15 , -21.32 , and -23.44 Kcal/mol, and it formed good binding interactions with their active sites. Compound 5 exhibited strong binding interactions with the amino acids Lys721, Cys773, and Leu694 inside EGFR. It formed two H-bond interactions with Val882 inside the PI3K active site, and it formed two arene-cation interactions with Lys89 inside the CDK2 active site like the co-crystallized ligands. These outcomes corroborated the kinase inhibition experiment findings. Previous literature reported the downstream inhibition pathway of EGFR/PI3K/AKT, which is linked to CDK2 inhibition, as a promising target for inducing apoptosis in cancer cells [32].

□ Tumor weight (mg)

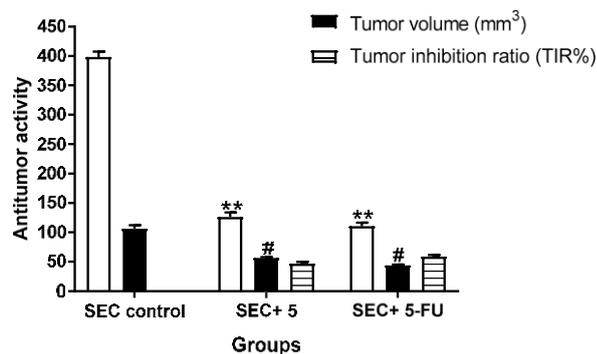

Figure 5. Measurements of antitumor potentiality in the SEC-bearing mice treated with compound 5 and 5-FU. "Mean \pm SD values of mice in each group ($n=6$). " **Values are highly significantly different ($p \leq 0.01$) between treated and SEC control", while "# values are significantly different ($p \leq 0.05$) between treated SEC and SEC control mice using the un-paired test in GraphPad prism". $TIR\% = C - T / C \times 100$.

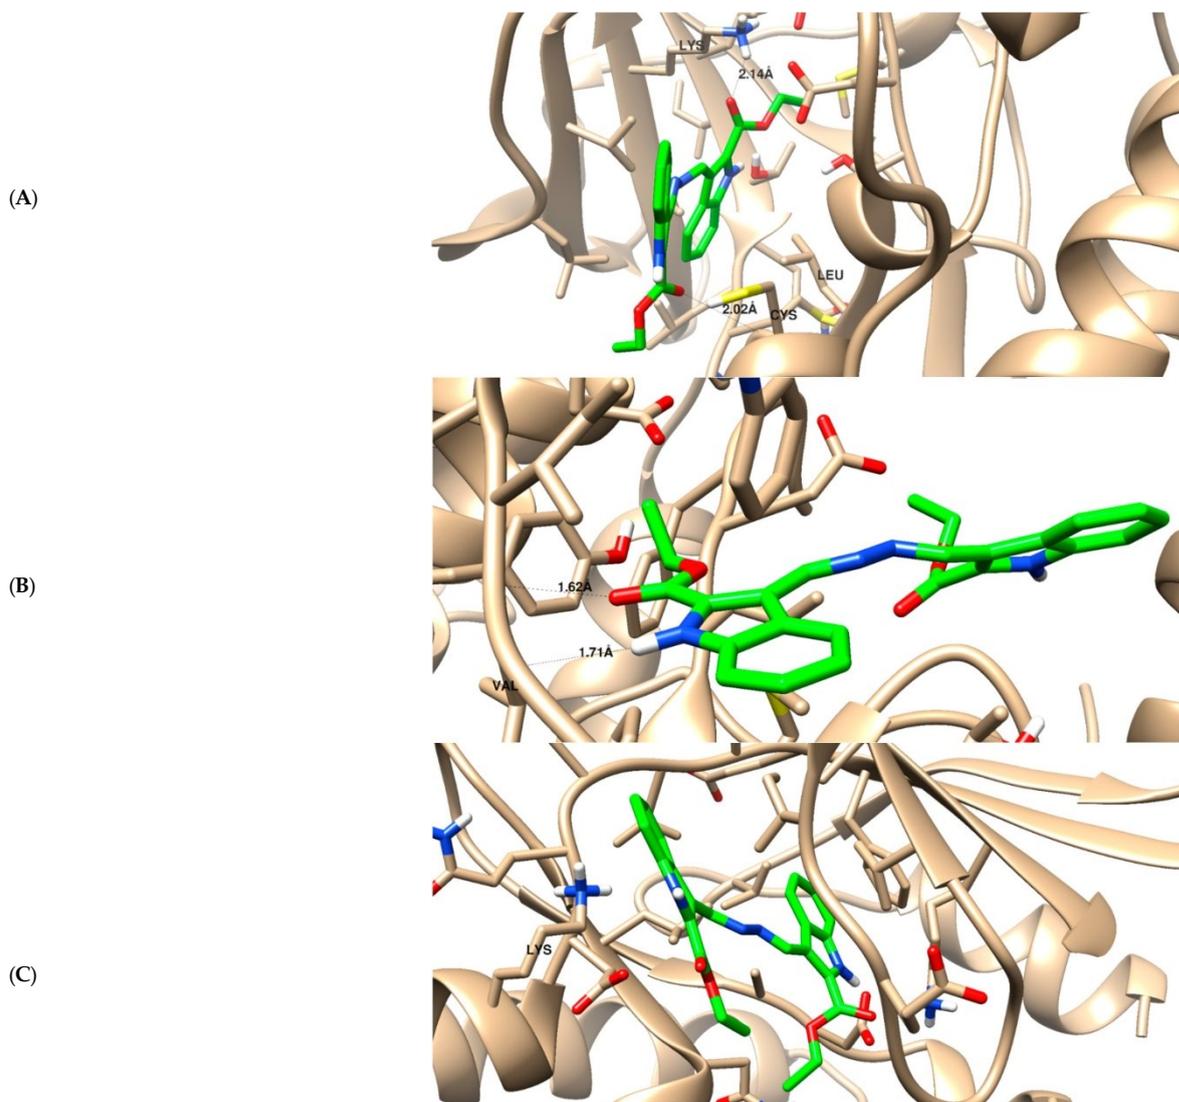

Figure 6. The binding disposition of docked compound 5 with ligand-receptor interactions inside the EGFR receptor (A), phosphoinositide 3-kinase (B), and cyclin-dependent kinase (C). Visualization was carried out using Chimera-UCSF.

As summarized in Figure 7, compound 5, as an indolyl-hydrazone derivative, induced potent cytotoxicity against MCF-7 as an apoptosis inducer through the downstream pathway of EGFR/PI3K/AKT and CDK2 inhibition. The effective pathway induced cell cycle arrest at the S-phase, and it led to apoptosis in the MCF-7 cells. EGFR, and its downstream pathway is considered one of the promising effective pathways for cancer treatment, and our results agreed with previous reported studies for the same compounds' scaffold affecting cytotoxic activities through apoptosis [33–35].

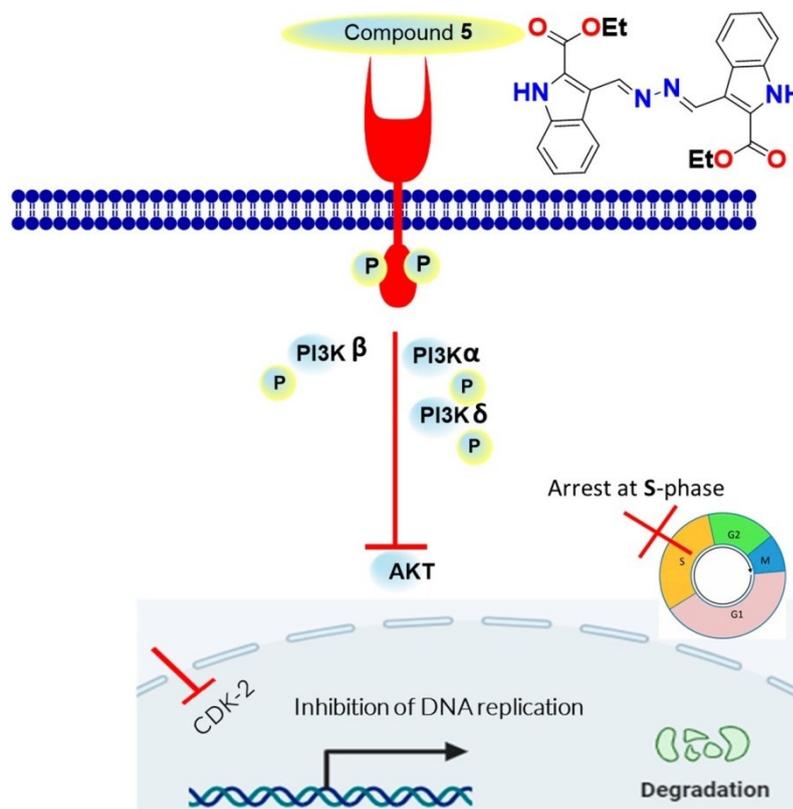

Figure 7. Schematic diagram for the mechanistic pathway for EGFR/PI3K/CDK2 inhibition as apoptosis inducers.

SAR

The structure–reactivity relationship of the synthesized compounds is summarized as follows in Figure 8: The hydrazone derivative **10**, featuring a *p*-nitro group-substituted benzene ring, exhibited the lowest reactivity, with an IC_{50} value of $25.4 \pm 1.54 \mu\text{M}$. In contrast, the aldehyde-based indole derivative **1**, the starting material, demonstrated better reactivity, with an IC_{50} value of $19.7 \pm 2.31 \mu\text{M}$. The thiosemicarbazide **3** and its isosteric semicarbazide **6** enhanced reactivity, with IC_{50} values of 9.42 ± 0.57 and $10.2 \pm 0.53 \mu\text{M}$, respectively. The presence of two nitro groups on the substituted benzene ring of hydrazone **12** significantly improved reactivity, with an IC_{50} value of $7.03 \pm 0.37 \mu\text{M}$, due to the high electron-withdrawing group effect. The introduction of the thio-triazole indole-based Schiff base **8** significantly increased activity ($IC_{50} = 4.38 \pm 0.23 \mu\text{M}$) up to 1.9-fold higher than the reference drug, while the symmetrical *bis*-esters azine **5** emerged as the most potent compound in inhibiting breast cancer cells, with an IC_{50} of $2.73 \pm 0.14 \mu\text{M}$, 3-fold more potent than the standard drug staurosporine ($IC_{50} = 8.32 \pm 0.43 \mu\text{M}$).

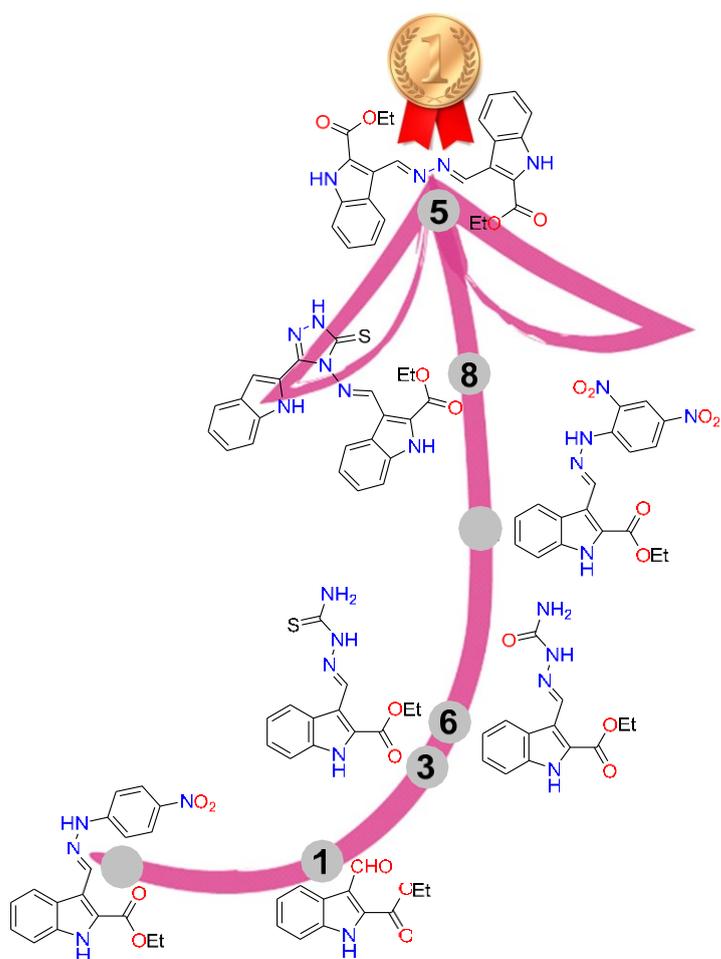

Figure 8. SAR for the synthesized compounds.

3. Materials and Methods

Chemistry

General

The values for the melting points were uncorrected and were determined in open capillaries using a Temp-melt II melting point equipment. On silica gel 60 (230–400 mesh ASTM), flash chromatography was carried out. On silica gel 60 F254 aluminum plates (E. Merck, layer thickness 0.2 mm), thin-layer chromatography (TLC) was performed. The spots were found using a UV lamp. Using DMSO- d_6 and $CDCl_3$ as solvents, the 1H and ^{13}C -NMR spectra were captured on Bruker instruments at 400 MHz for 1H NMR and 101 MHz for ^{13}C NMR, respectively. Using KBr and a PerkinElmer 1430 ratio-recording infrared spectrophotometer, Bruker's Fourier-transform infrared (FT-IR) spectrophotometry was used to record the IR spectra.

Synthesis

A mixture of **1** (1.0 mmol, 0.22 g), thiosemicarbazide, and semicarbazide.HCl (1.1 mmol, 0.1 g, and 0.12 g respectively) was grinded and fused on a hot plate for 5 min until all reactants turned to products. The products were purified by recrystallization from DMF/EtOH to **3** and **5**, respectively.

Ethyl (*E*)-3-((2-carbamothioylhydrazineylidene)methyl)-1*H*-indole-2-carboxylate **3**. There was 81% yield, 0.23 g, and m.p. 229–230 °C. 1H NMR (400 MHz, DMSO- d_6):

X-rayStructureDetermination

The general protocol for the collection of crystalline compounds 3and 5is provided in the supporting materials [36–38].

4. Cytotoxicity

The breast cancer (MCF-7) cells were obtained and cultivated in RPMI-1640 medium L-glutamine (Lonza Verviers SPRL, Verviers, Belgium, cat#12-604F) using a donation from the National Research Institute in Egypt.Each of the two cell lines was injected with 10% foetal bovine serum (FBS; Sigma-Aldrich, St. Louis, MO, USA) and 1% penicillin-streptomycin (Lonza, Belgium). Following standard tissue culture procedures, all cells were cultivated at 37 °C in 5% CO₂ humidified. On the second day of culture, cells were exposed to substances at concentrations of 0.01, 0.1, 1, 10, and 100 μ M.The MTT solution (Promega, Madison, WI, USA) was used to assess cell viability after 48 hours [38].After adding 20 μ L of MTT dye to each well, the plate was incubated for three hours.After that, absorbance was measured at 570 nm using the ELISA microplate reader (BIO-RAD, modeliMark, Tokyo, Japan). The percentage of cell viability was computed as (mean absorbance of tested compound)/(mean absorbance incontrol) \times 100, in comparison to the control. Lastly, the nonlinear dose–response sigmoidal curve in GraphPad Prism 7 was used to get the IC₅₀ values [39].Examination of Apoptosis Analysis of the cell cycle and Annexin V/PI staining Six-well culture plates were filled with 3–105 MCF-7 cells, and the plates were left in the incubator overnight.After that, cells were exposed to compound 5 at its IC₅₀ values for 48 hours.The cells and medium supernatants were then collected after PBS had been washed with ice-cold water.The cells were suspended in 100 L of annexin-binding buffer solution, which was made up of 25 mM CaCl₂, 1.4 M NaCl, and 0.1 M HEPES/NaOH, pH 7.4, and then treated with "AnnexinV-FITCsolution(1:100)andpropidiumiodide(PI)" at a concentration of 10 g/mL for 30 minutes in the dark. The Cytoflex FACS system was then used to gather labelled cells.The cytExpert tool was used to evaluate the data [39].ScratchAssay's Wound-Healing Assay Previous research mentioned the wound-healing test [40, 41].Four 105 MCF-7 cells were added to six-well plates with starvation medium, and the plates were then incubated for the whole night at 37 °C. Once it was determined the next day that the cells had adhered to the well and that cell confluence had reached 90%, a sterile 1 mL pipette tip was used to agitate a scratch-chop of the cell monolayer. Before the cells were taken off the plates, they were cleaned using starvation medium.The cells with the IC₅₀ of compounds 5, 8, and 12 in the complete medium were cultured for 48 hours in a CO₂ incubator.The medium was switched to PBS right away after 48

hours, the wound gap was inspected, and both control and treated cells were photographed using a digital camera that was connected to an Olympus microscope. Measurements were made of the area where the wound closes [42, 43]. As directed by the manufacturer, an ELISA kit was used to perform kinase inhibitory assays for EGFR (catalogue #40321), CDK2 (catalogue #79599), AKT (catalogue #78038), PI3K- α (catalogue #40639), β (catalogue #79802), and δ (catalogue #40628). Kinase inhibitory experiments were performed to evaluate compound 5's inhibitory efficacy against the kinase activity. The percentage that chemicals inhibited autophosphorylation was calculated using the formula $100 - [(A_{\text{Control}})/(A_{\text{Treated}}) - A_{\text{Control}}]$. The IC₅₀ was computed using the percentage inhibition curves of five different chemical doses using the GraphPad Prism7 tool [44]. The experimental approach was approved by the Suez Canal University Research Ethics Committee in InVivo (SEC-Bearing Model) (permission number REC219/2023, Faculty of Science, Suez Canal University) [45,46]. The Supplementary Materials provide support for the whole, comprehensive approach. Molecular Docking Maestro is used to build, optimise, and favour structures in an energetic manner. Following normal work, the AutoDock Vina 1.2.0 program was used to do a molecular docking analysis on the X-ray crystallographic structures of EGFR kinase (PDB ID: 1M17), PI3K (PDB = 1E7V), and CDK2 (PDB = 2A4L) [47,48]. The Chimera-UCSF 1.17.3 software was then used.

5. Conclusions

In order to find new bioactive lead compounds, ethyl 3-formyl-1H-indole-2-carboxylate acts as a precursor in a series of condensation processes conducted under fusion circumstances. We achieved structure assignments using NMR and X-ray single-crystal analysis. Most of the substances that were synthesised had significant anti-breast cancer properties. When compared to the usual medication, compounds 5, 8, and 12 shown greater activity. With IC₅₀ values of $2.73 \pm 0.14 \mu\text{M}$, compound 5 showed strong cytotoxicity, three times more effective than staurosporine (IC₅₀ = $8.32 \pm 0.43 \mu\text{M}$). With a 48.8% wound-closure rate, it also demonstrated strong wound-healing activity. In contrast to their respective conventional medications, compound 5 significantly boosted cell death by apoptosis induction by inhibiting PI3K- α , PI3K- β , PI3K- δ , CDK2, AKT-1, and EGFR kinases. As a result, it is advised that the recently discovered lead molecule be developed further as an anti-breast cancer treatment that targets kinases.
